RTP/RTCP Extension for RTP Splicing Notification

Abstract

Content splicing is a process that replaces the content of a main multimedia stream with other multimedia content and that delivers the substitutive multimedia content to the receivers for a period of time. The splicer is designed to handle RTP splicing and needs to know when to start and end the splicing.

This memo defines two RTP/RTCP extensions to indicate the splicing-related information to the splicer: an RTP header extension that conveys the information "in band" and an RTP Control Protocol (RTCP) packet that conveys the information out of band.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at https://www.rfc-editor.org/info/rfc8286.

Table of Contents

1. Introduction

Splicing is a process that replaces some multimedia content with other multimedia content and delivers the substitutive multimedia content to the receivers for a period of time. In some predictable splicing cases, e.g., advertisement insertion, the splicing duration needs to be inside of the specific pre-designated time slot. Certain timing information about when to start and end the splicing must be first acquired by the splicer in order to start the splicing. This document refers to this information as the "Splicing Interval".

[SCTE35] provides a method that encapsulates the Splicing Interval inside the MPEG2-TS (MPEG2 transport stream) layer in cable TV systems. When transported in RTP, a middlebox designed as the splicer to decode the RTP packets and search for the Splicing Interval inside the payloads is required. The need for such processing increases the workload of the middlebox and limits the number of RTP sessions the middlebox can support.

This document defines an RTP header extension [RFC8285] used by the main RTP sender to provide the Splicing Interval by including it in the RTP packets.

However, the Splicing Interval conveyed in the RTP header extension might not reach the splicer successfully. Any splicing-unaware middlebox on the path between the RTP sender and the splicer might strip this RTP header extension.

To increase robustness against such a case, this document also defines a new RTP Control Protocol (RTCP) packet type to carry the same Splicing Interval to the splicer. Since RTCP is also unreliable and may not be as "immediate" as the in-band technique, it’s only considered to be a complement to the RTP header extension.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

In addition, we define the following terms:

Main RTP Sender:

The sender of RTP packets carrying the main RTP stream.

Splicer:

An intermediary node that inserts substitutive content into a main RTP stream. The splicer sends substitutive content to the RTP receiver instead of the main content during splicing. It is also responsible for processing RTCP traffic between the RTP sender and the RTP receiver.

Splicing-In Point:

A virtual point in the RTP stream, suitable for substitutive content entry, typically in the boundary between two independently decodable frames.

Splicing-Out Point:

A virtual point in the RTP stream, suitable for substitutive content exit, typically in the boundary between two independently decodable frames.

Splicing Interval:

The NTP timestamps, representing the main RTP sender wallclock time, for the splicing-in point and splicing-out point per [RFC6828], allowing the splicer to know when to start and end the RTP splicing.

Substitutive RTP Sender:

The sender of RTP packets carrying the RTP stream that will replace the content in the main RTP stream.

2. Overview

2.1. Overview of RTP Splicing

RTP splicing is intended to replace some multimedia content with certain substitutive multimedia content and then forward it to the receivers for a period of time. This process is authorized by the main RTP sender that offers a specific time window for inserting the substitutive multimedia content in the main content. A typical usage

scenario is where an IPTV service provider uses its own regional advertising content to replace national advertising content, the time window of which is explicitly indicated by the IPTV service provider.

The splicer is a middlebox handling RTP splicing. It receives the main content and substitutive content simultaneously but only chooses to send one of them to the receiver at any point in time. When RTP splicing begins, the splicer sends the substitutive content to the receivers instead of the main content. When RTP splicing ends, the splicer switches back to sending the main content to the receivers. This implies that the receiver is explicitly configured to receive the traffic via the splicer and will return any RTCP feedback to it in the presence of the splicer.

The middlebox working as the splicer can be implemented as either an RTP mixer or an RTP translator. If implemented as an RTP mixer, the splicer will use its own synchronization source (SSRC), sequence number space, and timing model when generating the output stream to receivers, using the contributing source (CSRC) list to indicate whether the original content or substitutive content is being delivered. The splicer, on behalf of the content provider, can omit the CSRC list from the RTP packets it generates. This simplifies the design of the receivers, since they don't need to parse the CSRC list, but makes it harder to determine when the splicing is taking place (it requires inspection of the RTP payload data, rather than just the RTP headers). A splicer working as an RTP mixer splits the flow between the sender and receiver into two, and it requires separate control loops for RTCP and congestion control. [RFC6828] provides an example of an RTP mixer approach.

A splicer implemented as an RTP translator [RFC3550] will forward the RTP packets from the original and substitutive senders with their SSRCs intact but will need to rewrite RTCP Sender Report (SR) packets to account for the splicing. In this case, the congestion control loops run between the original sender and receiver and between the substitutive sender and receiver. The splicer needs to ensure that the RTCP feedback messages from the receiver are passed to the right sender to let the congestion control work.

2.2. Overview of Splicing Interval

To handle splicing on the RTP layer at the reserved time slots set by the main RTP sender, the splicer must first know the Splicing Interval from the main RTP sender before it can start splicing.

When a new splicing is forthcoming, the main RTP sender needs to send the Splicing Interval to the splicer. The Splicing Interval SHOULD be sent by the RTP header extension or RTCP extension message more

than once to mitigate possible packet loss. To enable the splicer to get the substitutive content before the splicing starts, the main RTP sender MUST send the Splicing Interval well in advance. For example, the main RTP sender can estimate when to send the Splicing Interval based on the round-trip time (RTT), following the mechanisms described in Section 6.4.1 of [RFC3550] when the splicer sends an RTCP Receiver Report (RR) to the main sender.

The substitutive sender also needs to learn the Splicing Interval from the main RTP sender in advance and estimate when to transfer the substitutive content to the splicer. The Splicing Interval could be transmitted from the main RTP sender to the substitutive content using some out-of-band mechanisms -- for example, a proprietary mechanism to exchange the Splicing Interval -- or the substitutive sender is implemented together with the main RTP sender inside a single device. To ensure that the Splicing Interval is valid for both the main RTP sender and the substitutive RTP sender, the two senders MUST share a common reference clock so that the splicer can achieve accurate splicing. The requirements for the common reference clock (e.g., resolution, skew) depend on the codec used by the media content.

In this document, the main RTP sender uses a pair of NTP timestamps to indicate when to start and end the splicing to the splicer: the timestamp of the first substitutive RTP packet at the splicing-in point and the timestamp of the first main RTP packet at the splicing-out point.

When the substitutive RTP sender gets the Splicing Interval, it must prepare the substitutive stream. The main content provider and the substitutive content provider MUST ensure that the RTP timestamp of the first substitutive RTP packet that would be presented to the receivers corresponds to the same time instant as the former NTP timestamp in the Splicing Interval. To enable the splicer to know the first substitutive RTP packet it needs to send, the substitutive RTP sender MUST send the substitutive RTP packet ahead of the splicing-in point, allowing the splicer to find out the timestamp of this first RTP packet in the substitutive RTP stream, e.g., using a prior RTCP SR message.

When it is time for the splicing to end, the main content provider and the substitutive content provider MUST ensure that the RTP timestamp of the first main RTP packet that would be presented on the receivers corresponds to the same time instant as the latter NTP timestamp in the Splicing Interval.

3. Conveying Splicing Interval in RTP/RTCP Extensions

This memo defines two backward-compatible RTP extensions to convey the Splicing Interval to the splicer: an RTP header extension and an RTCP splicing notification message.

3.1. RTP Header Extension

The RTP header extension mechanism defined in [RFC8285] can be adapted to carry the Splicing Interval, which consists of a pair of NTP timestamps.

This RTP header extension carries the 7 octets of the splicing-out NTP timestamp (lower 24-bit part of the "Seconds" of an NTP timestamp and the 32 bits of the "Fraction" of an NTP timestamp as defined in [RFC5905]), followed by the 8 octets of the splicing-in NTP timestamp (64-bit NTP timestamp as defined in [RFC5905]). The top 8 bits of the splicing-out NTP timestamp are inferred from the top 8 bits of the splicing-in NTP timestamp, assuming that (1) the splicing-out time is after the splicing-in time and (2) the Splicing Interval is less than 2^25 seconds. Therefore, if the value of the 7 octets of the splicing-out NTP timestamp is smaller than the value of the 7 lower octets of the splicing-in NTP timestamp, it implies a wrap of the 56-bit splicing-out NTP timestamp, which means that the top 8-bit value of the 64-bit splicing-out NTP timestamp is equal to the top 8-bit value of the splicing-in NTP timestamp plus 0x01. Otherwise, the top 8 bits of the splicing-out NTP timestamp are equal to the top 8 bits of the splicing-in NTP timestamp.

This RTP header extension can be encoded using either the one-byte or two-byte header defined in [RFC8285]. Figures 1 and 2 show the Splicing Interval header extension with each of the two header formats.

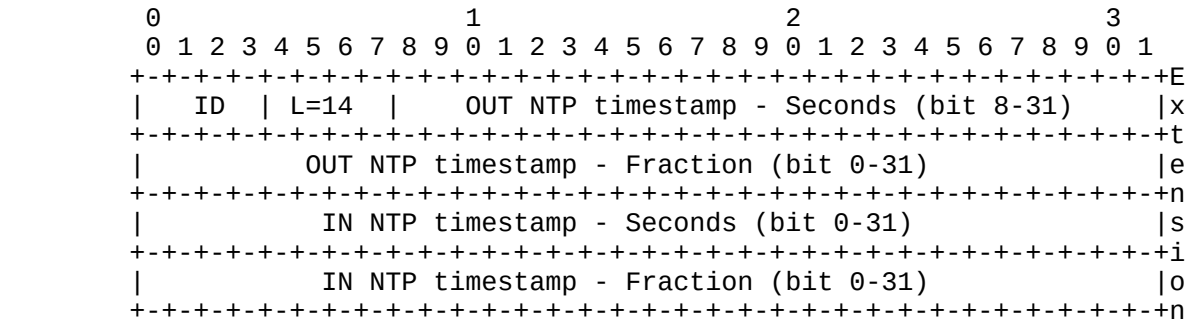

Figure 1: Splicing Interval Using the One-Byte Header Format

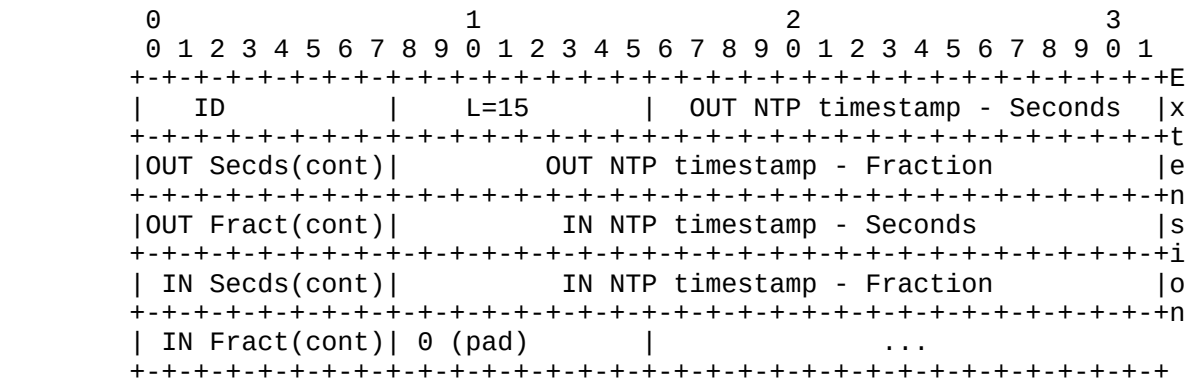

Figure 2: Splicing Interval Using the Two-Byte Header Format

Since the inclusion of an RTP header extension will reduce the efficiency of RTP header compression, it is RECOMMENDED that the main sender insert the RTP header extensions into a number of RTP packets, instead of all of the RTP packets, prior to the splicing-in.

After the splicer obtains the RTP header extension and derives the Splicing Interval, it generates its own stream and is not allowed to include the RTP header extension in outgoing packets; this reduces header overhead.

3.2. RTCP Splicing Notification Message

In addition to including the RTP header extension, the main RTP sender includes the Splicing Interval in an RTCP splicing notification message. Whether or not the timestamps are included in the RTP header extension, the main RTP sender MUST send the RTCP splicing notification message. This provides robustness in the case where a middlebox strips RTP header extensions. The main RTP sender

MUST make sure that the splicing information contained in the RTCP splicing notification message is consistent with the information included in the RTP header extensions.

The RTCP splicing notification message is a new RTCP packet type. It has a fixed header followed by a pair of NTP timestamps:

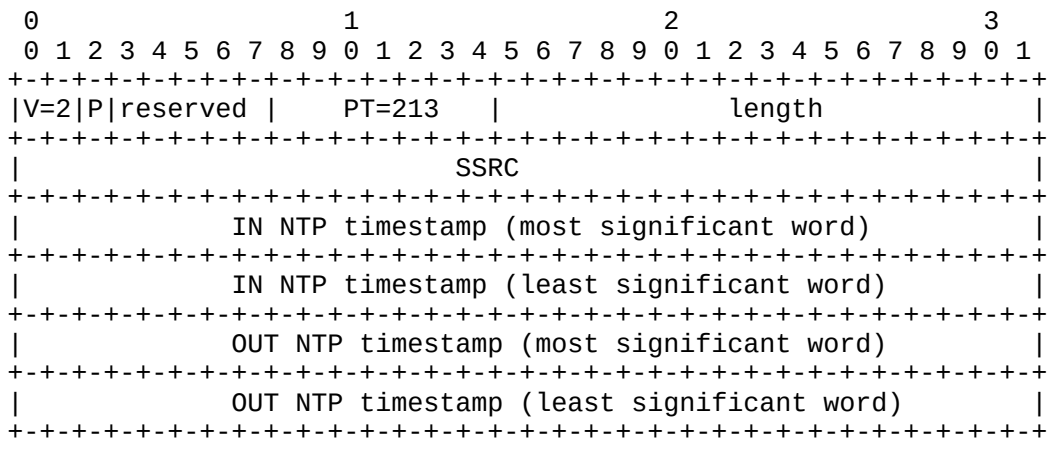

Figure 3: RTCP Splicing Notification Message

The RTCP splicing notification message includes the following fields:

Length: 16 bits

As defined in [RFC3550], the length of the RTCP packet in 32-bit words minus one, including the header and any padding.

SSRC: 32 bits

The SSRC of the main RTP sender.

Timestamp: 64 bits

Indicates the wallclock time when this splicing starts and ends. The full-resolution NTP timestamp is used, which is a 64-bit unsigned fixed-point number with the integer part in the first 32 bits and the fractional part in the last 32 bits. This format is the same as the NTP timestamp field in the RTCP SR (Section 6.4.1 of [RFC3550]).

The RTCP splicing notification message can be included in the RTCP compound packet together with the RTCP SR generated at the main RTP sender; hence, it follows the compound RTCP rules defined in Section 6.1 in [RFC3550].

If the use of non-compound RTCP [RFC5506] was previously negotiated between the sender and the splicer, the RTCP splicing notification messages may be sent as non-compound RTCP packets. In some cases where the mapping from the RTP timestamp to the NTP timestamp changes, e.g., clock drift happens before the splicing event, sending an RTCP SR or even updated Splicing Interval information in a timely manner might be required in order to update the timestamp mapping for accurate splicing.

Since the RTCP splicing notification message is intentionally sent by the main RTP sender to the splicer, the splicer is not allowed to forward this message to the receivers, so as to avoid useless processing and additional RTCP bandwidth consumption in the downstream receivers.

4. Reducing Splicing Latency

When splicing starts or ends, the splicer outputs the multimedia content from another sender to the receivers. Given that the receivers must first acquire certain information ([RFC6285] refers to this information as "Reference Information") to start processing the multimedia data, either the main RTP sender or the substitutive sender SHOULD provide the Reference Information together with its multimedia content to reduce the delay caused by acquiring the Reference Information. The methods by which the Reference Information is distributed to the receivers are out of scope for this memo.

Another latency element is delay caused by synchronization. The receivers must receive enough synchronization metadata prior to synchronizing the separate components of the multimedia streams when splicing starts or ends. Either the main RTP sender or the substitutive sender SHOULD send the synchronization metadata early enough so that the receivers can play out the multimedia in a synchronized fashion. The main RTP sender or the substitutive sender can estimate when to send the synchronization metadata based on, for example, the RTT, following the mechanisms described in Section 6.4.1 of [RFC3550] when the splicer sends an RTCP RR to the main sender or the substitutive sender. The main RTP sender and the substitutive sender can also be coordinated by some proprietary out-of-band mechanisms to decide when, and to whom, the metadata is to be sent. If both send the information, the splicer SHOULD pick one based on the current situation, e.g., choosing either (1) the main RTP sender

when synchronizing the main media content or (2) the information from the substitutive sender when synchronizing the spliced content. To reduce possible synchronization delay, it is RECOMMENDED that the mechanisms defined in [RFC6051] be adopted.

5. Failure Cases

This section examines the implications of losing RTCP splicing notification messages, e.g., the RTP header extension is stripped on the path.

Given that there may be a splicing-unaware middlebox on the path between the main RTP sender and the splicer, the main and substitutive RTP senders can use one heuristic to verify whether or not the Splicing Interval reaches the splicer.

The splicer can be implemented to have its own SSRC and send RTCP reception reports to the senders of the main and substitutive RTP streams. This allows the senders to detect problems on the path to the splicer. Alternatively, it is possible to implement the splicer such that it has no SSRC and does not send RTCP reports; this prevents the senders from being able to monitor the quality of the path to the splicer.

If the splicer has an SSRC and sends its own RTCP reports, it can choose not to pass RTCP reports it receives from the receivers to the senders. This will prevent the senders from being able to monitor the quality of the paths from the splicer to the receivers.

A splicer that has an SSRC can choose to pass RTCP reception reports from the receivers back to the senders, after modifications to account for the splicing. This will allow the senders to monitor the quality of the paths from the splicer to the receivers. A splicer that does not have its own SSRC has to forward and translate RTCP reports from the receiver; otherwise, the senders will not see any receivers in the RTP session.

If the splicer is implemented as a mixer, it will have its own SSRC, send its own RTCP reports, and forward translated RTCP reports from the receivers.

Upon the detection of a failure, the splicer can communicate with the main sender and the substitutive sender via some out-of-band signaling technique and fall back to the payload-specific mechanisms it supports, e.g., the MPEG2-TS splicing solution defined in [SCTE35], or just abandon the splicing.

6. Session Description Protocol (SDP) Signaling

This document defines the URI for declaring this header extension in an "extmap" attribute to be "urn:ietf:params:rtp-hdrext:splicing-interval".

This document extends the standard semantics defined in "The Session Description Protocol (SDP) Grouping Framework" [RFC5888] with a new semantic, called "SPLICE", to represent the relationship between the main RTP stream and the substitutive RTP stream. Only two "m=" lines are allowed in the SPLICE group. The main RTP stream is the one with the extended "extmap" attribute, and the other one is the substitutive stream. A single "m=" line MUST NOT be included in different SPLICE groups at the same time. The main RTP sender provides the information about both main and substitutive sources.

The extended SDP attribute specified in this document is applicable for offer/answer content [RFC3264] and does not affect any rules when negotiating offers and answers. When used with multiple "m=" lines, substitutive RTP MUST be applied only to the RTP packets whose SDP "m=" line is in the same group with the substitutive stream using SPLICE and has the extended splicing "extmap" attribute. This semantic is also applicable for BUNDLE cases.

The following examples show how SDP signaling could be used for splicing in different cases.

6.1. Declarative SDP

```

Figure 4: Example SDP for a Single-Channel Splicing Scenario

The splicer receiving the SDP message above receives one MPEG2-TS stream (payload 100) from the main RTP sender (with a multicast destination address of 233.252.0.1) on port 30000 and/or receives another MPEG2-TS stream from the substitutive RTP sender (with a multicast destination address of 233.252.0.2) on port 30002. But at a particular point in time, the splicer only selects one stream and outputs the content from the chosen stream to the downstream receivers.

6.2. Offer/Answer without BUNDLE

SDP Offer - from the main RTP sender:

```

6.3. Offer/Answer with BUNDLE: All Media Are Spliced

In this example, the bundled audio and video media have their own substitutive media for splicing:

1. An offer, in which the offerer assigns a unique address and a substitutive media to each bundled "m=" line for splicing within the BUNDLE group.

2. An answer, in which the answerer selects its own BUNDLE address and leaves the substitutive media untouched.

SDP Offer - from the main RTP sender:

```

7. Security Considerations

The security considerations of the RTP specification [RFC3550] and the general mechanism for RTP header extensions [RFC8285] apply. The splicer can be either a mixer or a translator, and all the security considerations of topologies [RFC7667] [RFC7201] for these two types of RTP intermediaries are applicable for the splicer.

The splicer replaces some content with other content in RTP packets, thus breaking any RTP-level end-to-end security, such as source authentication and integrity protection. End-to-end source authentication is not possible with any known existing splicing solution. A new solution can theoretically be developed that enables identification of the participating entities and what each provides, i.e., the different media sources -- main and substitutive -- and the splicer, which provides the RTP-level integration of the media payloads in a common timeline and synchronization context.

Since the splicer breaks RTP-level end-to-end security, it needs to be part of the signaling context and the necessary security associations (e.g., Secure Real-time Transport Protocol (SRTP)

[RFC3711] crypto contexts) established for the RTP session participants. When using SRTP, the splicer would have to be provisioned with the same security association as the main RTP sender.

If there are concerns about the confidentiality of the splicing time information, the header extension defined in this document MUST also be protected; for example, header extension encryption [RFC6904] can be used in this case. However, the malicious endpoint may get the splicing time information by other means, e.g., inferring it from the communication between the main and substitutive content sources. To avoid the insertion of invalid substitutive content, the splicer MUST have some mechanisms to authenticate the substitutive stream source.

For cases where the splicing time information is changed by a malicious endpoint, the splicing, for example, may fail, since it will not be available at the right time for the substitutive media to arrive. Another case is one where an attacker may prevent the receivers from receiving the content from the main sender by inserting extra splicing time information. To avoid the above scenarios, the authentication of the RTP header extension for splicing time information SHOULD be considered.

When a splicer implemented as a mixer sends the stream to the receivers, the CSRC list, which can be used to detect RTP-level forwarding loops as defined in Section 8.2 of [RFC3550], may be removed for simplifying the receivers that cannot handle multiple sources in the RTP stream. Hence, loops may occur, causing packets to loop back to a point upstream of the splicer and possibly forming a serious denial-of-service threat. In such a case, non-RTP means, e.g., signaling among all the participants, MUST be used to detect and resolve loops.

8. IANA Considerations

8.1. RTCP Control Packet Types

Based on the guidelines suggested in [RFC8126], a new RTCP packet format has been registered in the "RTCP Control Packet types (PT)" registry:

Name: SNM

Long name: Splicing Notification Message

Value: 213

Reference: This document

8.2. RTP Compact Header Extensions

IANA has registered a new RTP Compact Header Extension [RFC8285], according to the following:

Extension URI: urn:ietf:params:rtp-hdrext:splicing-interval

Description: Splicing Interval

Contact: Jinwei Xia <xiajinwei@huawei.com>

Reference: This document

8.3. SDP Grouping Semantic Extension

IANA has registered the new SDP grouping semantic extension called "SPLICE" in the "Semantics for the ’group’ SDP Attribute" subregistry of the "Session Description Protocol (SDP) Parameters" registry:

Semantics: Splice

Token: SPLICE
